# Maximal Codeword Lengths in Huffman Codes 

Y. S. Abu-Mostafa and R. J. McEliece<br>Department of Electrical Engineering, California Institute of Technology MS 136-93, Pasadena, CA 91125, U.S.A.

In celebration of the $60^{\text {th }}$ birthday of Solomon W. Golomb

#### Abstract

In this paper, we consider the following question about Huffman coding, which is an important technique for compressing data from a discrete source. If $p$ is the smallest source probability, how long, in terms of $p$, can the longest Huffman codeword be? We show that if $p$ is in the range $0<p \leq 1 / 2$, and if $K$ is the unique index such that $1 / F_{K+3}<p \leq 1 / F_{K+2}$, where $F_{K}$ denotes the $K^{\text {th }}$ Fibonacci number, then the longest Huffman codeword for a source whose least probability is $p$ is at most $K$, and no better bound is possible. Asymptotically, this implies the surprising fact that for small values of $p$, a Huffman code's longest codeword can be as much as $44 \%$ larger than that of the corresponding Shannon code. © 2000 Elsevier Science Ltd. Keywords-Data compression, Huffman codes, Fibonacci numbers.

## 1. INTRODUCTION AND SUMMARY

Huffman coding is optimal (in the sense of minimizing average codeword length) for any discrete memoryless source, and Huffman codes are in widespread use in data compression applications. In many situations, it would be useful to have an easy way to estimate the longest Huffman codeword length for a given source without having to go through Huffman's algorithm, but since there is no known closed-form expression for the Huffman codeword lengths, no such estimate immediately suggests itself. However, since the longest codeword will always be associated with the least probable source symbol, one way to address this problem is to ask the following question. If $p$ is the smallest source probability, how long, in terms of $p$, can the longest Huffman codeword be? It turns out that this quantity, which we denote by $L(p)$, is easy to calculate, and so $L(p)$ provides an "easy estimate" of the longest Huffman codeword length.

Our formula for $L(p)$ involves the famous Fibonacci numbers $\left(F_{n}\right)_{n \geq 0}$, which are defined recursively as follows:

$$
\begin{equation*}
F_{0}=0, \quad F_{1}=1, \quad \text { and } \quad F_{n}=F_{n-1}+F_{n-2}, \quad \text { for } n \geq 2 \tag{1}
\end{equation*}
$$

Thus, we have $F_{2}=1, F_{3}=2, F_{4}=3, F_{5}=5, F_{6}=8$, etc. The Fibonacci numbers and their properties are discussed in detail in [1, Section 1.2.8]. Here is our main result. (Note that since

[^0]the definition of $L(p)$ assumes $p$ to be the smallest probability in a source, $p$ must lie in the range $0<p \leq 1 / 2$.)

Theorem 1. Let $p$ be a probability in the range $0<p \leq 1 / 2$, and let $K$ be the unique index such that

$$
\begin{equation*}
\frac{1}{F_{K+3}}<p \leq \frac{1}{F_{K+2}} . \tag{2}
\end{equation*}
$$

Then $L(p)=K$. Thus, $p \in(1 / 3,1 / 2]$ implies $L(p)=1, p \in(1 / 5,1 / 3]$ implies $L(p)=2$, $p \in(1 / 8,1 / 5]$ implies $L(p)=3$, etc.

It is easy to prove by induction that the Fibonacci numbers satisfy the following inequalities:

$$
\begin{equation*}
\phi^{n-2}<F_{n}<\phi^{n-1}, \quad \text { for } n \geq 3, \tag{3}
\end{equation*}
$$

where $\phi=(1+\sqrt{5}) / 2=1.618 \ldots$ is the "golden ratio". If we combine (3) with Theorem 1 , we see that

$$
\begin{equation*}
\log _{\phi} \frac{1}{p}-2<L(p)<\log _{\phi} \frac{1}{p} \tag{4}
\end{equation*}
$$

which in turn implies that

$$
\begin{equation*}
\lim _{p \rightarrow 0} \frac{L(p)}{\log _{\phi}(1 / p)}=1 \tag{5}
\end{equation*}
$$

Since $\log _{\phi} x=\left(\log _{2} x\right) /\left(\log _{2} \phi\right)=1.4404 \log _{2} x$, (5) implies the surprising fact that for small values of $p$, a Huffman code's longest codeword can be as much as $44 \%$ larger than that of the corresponding (in general, suboptimal) Shannon code [2, Chapter 5], which assigns a symbol with probability $p$ a codeword of length $\left\lceil\log _{2}(1 / p)\right\rceil$.

Theorem 1 is closely related to a result of Katona and Nemetz [3], which identifies the length of the longest possible Huffman codeword for a source symbol of probability $p$ (whether or not $p$ is the smallest source probability). Denote this quantity by $L^{*}(p)$, their result is as follows.
Theorem 2. (See [3].) Let $p$ be a probability in the range $0<p<1$, and let $K$ be the unique index such that

$$
\begin{equation*}
\frac{1}{F_{K+2}} \leq p<\frac{1}{F_{K+1}} . \tag{6}
\end{equation*}
$$

Then $L^{*}(p)=K$. Thus, $p \in[1 / 2,1)$ implies $L^{*}(p)=1, p \in[1 / 3,1 / 2)$ implies $L^{*}(p)=2$, $p \in[1 / 5,1 / 3)$ implies $L^{*}(p)=3$, etc.

Comparing Theorems 1 and 2 , we see that $L^{*}(p)=L(p)+1$ unless $p$ is the reciprocal of a Fibonacci number, in which case $L^{*}(p)=L(p) .{ }^{1}$

## 2. PROOF OF THEOREM 1

The proof of Theorem 1 is in two parts. First, we will show that if $p>1 / F_{K+3}$, then in any Huffman code for a source whose smallest probability is $p$, the longest codeword length is at most $K$. In fact, we will prove a considerably stronger result. We will define the class of efficient prefix codes, and observe that any Huffman code, and in fact any optimal code for a given source, is efficient. Then we will show that if $p>1 / F_{K+3}$, in any efficient code for a source whose smallest probability is $p$, the longest codeword length is at most $K$. In the second half of the proof, we will show that if $p \leq 1 / F_{K+2}$, there exists a source whose smallest probability is $p$, which has at least one Huffman code whose longest word has length $K$. As an extension, we will see that if $p<1 / F_{K+2}$, there exists a source whose smallest probability is $p$, and for which every optimal code has longest word of length $K$. (If $p=1 / F_{K+2}$, however, there is no such source.)

[^1]We come now to the definition of efficient prefix codes, which is best stated in terms of the associated binary code tree (see Figure 1). Each source symbol and its corresponding codeword is associated with a unique terminal node on the tree. Also, each node in the tree is assigned a probability. The probability of a terminal node is defined to be the probability of the corresponding source symbol, and the probability of any other node of the code tree is defined to be the sum of the probabilities of its two "children". The level of the root node is defined to be zero, and the level of every other node is defined to be one more than the level of its parent. Two nodes descended from the same parent node are called siblings. Figure 1 shows two different code trees for the source $[3 / 20,3 / 20,3 / 20,3 / 20,8 / 20]$. The tree in Figure 1a corresponds to the prefix code $\{000,001,01,10,11\}$, and the tree in Figure 1b corresponds to $\{000,001,010,011,1\}$.

Figure 1. Two code trees for the source $[3 / 20,3 / 20,3 / 20,3 / 20,8 / 20]$. The tree in (a) is efficient, but not optimal (average length $=2.3$ ); the one in (b) is optimal (average length $=2.2$ ).

Definition. A prefix code for a source $S$ is efficient if every node except the root in the code tree has a sibling, and if level $(v)<\operatorname{level}\left(v^{\prime}\right)$ implies $p(v) \geq p\left(v^{\prime}\right)$.

Gallager [4] noted that every Huffman tree is efficient, but in fact it is easy to see more generally that every optimal tree is efficient. This is because in an inefficient tree, with nodes $v$ and $v^{\prime}$ such that level $(v)<\operatorname{level}\left(v^{\prime}\right)$ but $p(v)<p\left(v^{\prime}\right)$, by interchanging the subtrees rooted at $v$ and $v^{\prime}$, we arrive at a new code tree for the same source, whose average length has been reduced by exactly $\left(\operatorname{level}\left(v^{\prime}\right)-\operatorname{level}(v)\right)\left(p\left(v^{\prime}\right)-p(v)\right)$. However, it is not true that every efficient code is optimal, as shown in Figure 1, which shows two different efficient code trees for the source [ $3 / 20,3 / 20,3 / 20,3 / 20,8 / 20]$. The code in Figure 1b is optimal, but the one in Figure 1a is not.
Theorem 3. If $p>1 / F_{K+3}$, then in any efficient prefix code for a source whose least probability is $p$, the longest codeword length is at most $K$.
Proof. We will prove the contrapositive, i.e., if $p$ is the least probability in a source which has an efficient prefix code whose longest word has length $\geq K+1$, then $p \leq 1 / F_{K+3}$.

Thus, we suppose that $S$ is a source whose least probability is $p$, and that there is an efficient prefix code for $S$ whose longest word is of length $\geq K+1$. In the code tree for this code, there must be a path of length $K+1$ starting from the terminal node corresponding to the longest word and moving upwards toward the root. This path is shown in Figure 2, as the path whose probabilities are $p_{0}, p_{1}, \ldots, p_{K+1}$. Since the code is assumed to be efficient, each of the vertices in this path (except possibly the top vertex) has a sibling; these siblings are shown in Figure 2, as having probabilities $q_{0}, q_{1}, \ldots, q_{K}$. Now we can prove the following:

$$
\begin{equation*}
p_{i} \geq F_{i+2} p, \quad \text { for } i=0,1, \ldots, K+1 . \tag{7}
\end{equation*}
$$

We prove (7) by induction. For $i=0$, (7) merely says that $p_{0} \geq p$, which is true since $p_{0}=p$ by definition. Also, note that $q_{0} \geq p$ since $p$ is the least source probability. Thus, $p_{1}=p_{0}+q_{0} \geq$

Figure 2. A portion of an efficient code tree, in which the longest codeword has length $\geq K+1$. $p_{0}$ is the least source probability.
$p+p=2 p=F_{3} p$, which proves (7) for $i=1$. For $i \geq 2$, we have $p_{i}=p_{i-1}+q_{i-1}$. But $p_{i-1} \geq F_{i+1} p$ by induction, and $q_{i-1} \geq p_{i-2}$ since the code is efficient ( $q_{i-1}$ is a higher level node than $p_{i-2}$ ). Thus, we have $q_{i-1} \geq p_{i-2} \geq F_{i} p$ by induction, and so $p_{i}=p_{i-1}+q_{i-1} \geq\left(F_{i+1}+F_{i}\right) p=F_{i+2} p$, which completes the proof of (7).
Now consider the probability $p_{K+1}$. On one hand, we have $p_{K+1} \leq 1$; but on the other hand $p_{K+1} \geq F_{K+3} p$, by (7). Combining these two inequalities, we have $p \leq 1 / F_{K+3}$, which completes the proof.
Theorem 4. If $p \leq 1 / F_{K+2}$, there exists a source whose smallest probability is $p$, and which has a Huffman code whose longest word has length $K$. If $p<1 / F_{K+2}$, there exists such a source for which every optimal code has a longest word of length $K$.
Proof. Consider the following set of $K+1$ source probabilities:

$$
\begin{equation*}
\left[p, \frac{F_{1}}{F_{K+2}}, \frac{F_{2}}{F_{K+2}}, \ldots, \frac{F_{K-1}}{F_{K+2}}, \frac{F_{K}+1}{F_{K+2}}-p\right] . \tag{8}
\end{equation*}
$$

Note that $p$ is the minimal probability for this source, since $p \leq 1 / F_{K+2}=F_{1} / F_{K+2}$. Now consider the code tree for this source depicted in Figure 3, which assigns the source probability $p$ a word of length $K$. This tree is in fact a Huffman tree for these probabilities, i.e., a code tree which arises when Huffman's algorithm is applied to the source (8). To see this, we first prove that the internal vertex probabilities $p_{i}$ in Figure 3 are given by the following formula:

$$
\begin{align*}
p_{i} & =\frac{F_{i+2}}{F_{K+2}}-h, \quad \text { for } i=0,1, \ldots, K-1,  \tag{9}\\
p_{K} & =1, \tag{10}
\end{align*}
$$

where $h=1 / F_{K+2}-p$.
To prove (9), we use induction. For $i=0$, we have by definition $p_{0}=p=1 / F_{K+2}-h=$ $F_{2} / F_{K+1}-h$. For $i \geq 1$, we then have $p_{i}=p_{i-1}+F_{i} / F_{K+2}=\left(F_{i+1} / F_{K+1}-h\right)+F_{i} / F_{K+2}=$ $F_{i+2} / F_{K+2}-h$. To prove (10), we note that $p_{K}=p_{K-1}+\left(F_{K}+1\right) / F_{K+2}-p$. But from (9) we have $p_{K-1}=\left(F_{K+1} / F_{K+2}-h\right)$, so that $p_{K}=\left(F_{K+1} / F_{K+2}-h\right)+\left(F_{K} / F_{K+2}+h\right)=F_{K+2} / F_{K+2}=1$. Thus, the probabilities in (8) sum to one.

It now follows that the tree in Figure 3 is a Huffman tree, for from (9) we see that at the $i^{\text {th }}$ stage ( $i=0, \ldots, K-1$ ), the "collapsed" source consists of the probabilities

$$
\begin{equation*}
\left[\frac{F_{i+2}}{F_{K+2}}-h, \frac{F_{i+1}}{F_{K+2}}, \frac{F_{i+2}}{F_{K+2}}, \ldots, \frac{F_{K-1}}{F_{K+2}}, \frac{F_{K}}{F_{K+2}}+h\right] . \tag{11}
\end{equation*}
$$

Figure 3. A Huffman code tree for the source in (8). Its smallest probability is $p$, where $p \leq 1 / F_{K+2}$, and its longest codeword length is $K$.

Plainly, the two leftmost probabilities in (11), viz, $F_{i+2} / F_{K+2}-h$ and $F_{i+1} / F_{K+2}$, are two of the smallest probabilities, and so the tree of Figure 3 is a Huffman tree, as asserted.

Finally, note that if $h>0$, i.e., if $p<1 / F_{K+2}$, the leftmost two probabilities in (11) are uniquely the two smallest probabilities in the list, so that the Huffman tree in Figure 3 is the unique Huffman tree for the source (8). And since the set of codeword lengths in any optimal code is the same as the set of lengths in some Huffman code, the last statement in Theorem 4 follows.

If we combine Theorems 3 and 4 , we get a result which is stronger than Theorem 1.
Example 1. Let $p=2^{-8}$. Then $1 / F_{14}=1 / 377<p<1 / F_{13}=1 / 233$, and so by Theorem 1 , $L\left(2^{-8}\right)=11$. More concretely, Theorem 3 shows that no Huffman code for a source whose smallest probability is $2^{-8}$ can have a codeword whose length is longer than 11. By Theorem 4, on the other hand, every optimal code for the source

$$
\begin{equation*}
\left[2^{-8}, \frac{1}{233}, \frac{1}{233}, \frac{2}{233}, \frac{3}{233}, \frac{5}{233}, \frac{8}{233}, \frac{13}{233}, \frac{21}{233}, \frac{34}{233}, \frac{55}{233}, \frac{90}{233}-2^{-8}\right] \tag{12}
\end{equation*}
$$

has a longest word of length 11.

## 3. EXTENSION OF THE KATONA-NEMETZ THEOREM

In this section, we will state without proof two theorems which, taken together, yield a result which is slightly stronger than Katona and Nemetz's Theorem 2 . The proofs are entirely similar to the proofs of Theorems 3 and 4.
Theorem 5. Let $S$ be a source containing a symbol a whose probability is $p$. If $p \geq 1 / F_{K+2}$, then in any efficient prefix code for $S$, the length of the codeword assigned to the symbol $a$ is at most $K$.
Theorem 6. Let $p<1 / F_{K+1}$. Then there exists a source $S$ containing a symbol a whose probability is $p$, and such that every optimal code for $S$ has assigned to a a codeword of length $K$. Explicitly, one such source is given by

$$
\begin{equation*}
S=\left[\frac{1}{F_{K+1}}-p-\epsilon, p, \frac{F_{1}}{F_{K+1}}, \frac{F_{2}}{F_{K+1}}, \ldots, \frac{F_{K-1}}{F_{K+1}}+\epsilon\right], \tag{13}
\end{equation*}
$$

where $\epsilon$ is any real number such that $0<\epsilon<1 / F_{K+1}-p$.
Example 2. Let $p=2^{-8}$. Then $1 / F_{14}=1 / 377<p<1 / F_{13}=1 / 233$, and so by Theorem 2, $L^{*}\left(2^{-8}\right)=12$. Indeed, by Theorem 6, every optimal code for the source

$$
\begin{equation*}
\left[\frac{1}{233}-2^{-8}-\epsilon, 2^{-8}, \frac{1}{233}, \frac{1}{233}, \frac{2}{233}, \frac{3}{233}, \frac{5}{233}, \frac{8}{233}, \frac{13}{233}, \frac{21}{233}, \frac{34}{233}, \frac{55}{233}, \frac{89}{233}+\epsilon\right], \tag{14}
\end{equation*}
$$

where $0<\epsilon<1 / 233-1 / 256$, assigns the symbol with probability $2^{-8}$ a codeword of length 12 .

[^1]:    ${ }^{1}$ In fact, however, if we were to make a subtle change in the definition of $L(p)$, this special case would disappear. The change required is to define $L(p)$ as the minimum maximum Huffman codeword length over all Huffman codes for a source with $p$ as the least probability, where the outer minimum is over all Huffman codes for a given source.
